#### **Chapter 4 Fundamental Data Types**

#### **CHAPTER GOALS**

- To understand integer and floating-point numbers
- To recognize the limitations of the numeric types
- To become aware of causes for overflow and roundoff errors
- To understand the proper use of constants
- To write arithmetic expressions in Java
- To use the String type to define and manipulate character strings
- To learn how to read program input and produce formatted output

This chapter teaches how to manipulate numbers and character strings in Java. The goal of this chapter is to gain a firm understanding of the fundamental Java data types.

You will learn about the properties and limitations of the number types in Java. You will see how to manipulate numbers and strings in your programs. Finally, we cover the important topic of input and output, which enables you to implement interactive programs.

133 134

# 4.1 Number Types

In Java, every value is either a reference to an object, or it belongs to one of the eight *primitive types* shown in <u>Table 1</u>.

Java has eight primitive types, including four integer types and two floating-point types.

Six of the primitive types are number types, four of them for integers and two for floating-point numbers.

Each of the integer types has a different range—Advanced Topic 4.2 explains why the range limits are related to powers of two. Generally, you will use the int type for integer quantities. However, occasionally, calculations involving integers can overflow. This happens if the result of a computation exceeds the range for the number type. For example:

A numeric computation overflows if the result falls outside the range for the number type.

```
int n = 1000000;
System.out.println(n * n); // Prints-727379968
```

The product  $n * n \text{ is } 10^{12}$ , which is larger than the largest integer (about  $2 \cdot 10^9$ ). The result is truncated to fit into an int, yielding a value that is completely wrong. Unfortunately, there is no warning when an integer overflow occurs.

# **Table 1 Primitive Types**

Туре	Description	Size
int	The integer type, with range –2,147,483,648 ···	4 bytes
	2,147,483,647 (about 2 billion)	
byte	The type describing a single byte, with range -128 ···	1 byte
	127	
short	The short integer type, with range -32768 ··· 32767	2 bytes
long	The long integer type, with range	8 bytes
	−9,223,372,036,854,775,808 ···	
	9,223,372,036,854,775,807	
double	The double-precision floating-point type, with a range	8 bytes
	of about ±10 <sup>308</sup> and about 15 significant decimal digits	
float	The single-precision floating-point type, with a range of	4 bytes
	about ±10 <sup>38</sup> and about 7 significant decimal digits	
char	The character type, representing code units in the	2 bytes
	Unicode encoding scheme (see Advanced Topic 4.5)	
boolean	The type with the two truth values false and true (see	1 bit
	<u>Chapter 5</u> )	

If you run into this problem, the simplest remedy is to use the long type. Advanced Topic 4.1 shows you how to use the arbitary-precision BigInteger type in the unlikely event that even the long type overflows.

Overflow is not usually a problem for double-precision floating-point numbers. The double type has a range of about  $\pm 10^{308}$  and about 15 significant digits. However, you want to avoid the float type—it has less than 7 significant digits. (Some programmers use float to save on memory if they need to store a huge set of numbers that do not require much precision.)

*Rounding errors* are a more serious issue with floating-point values. Rounding errors can occur when you convert between binary and decimal numbers, or between integers and floating-point numbers. When a value cannot be converted exactly, it is rounded to the nearest match. Consider this example:

Rounding errors occur when an exact conversion between numbers is not possible.

This problem is caused because computers represent numbers in the binary number system. In the binary number system, there is no exact representation of the fraction 1/10, just as there is no exact representation of the fraction 1/3 = 0.33333 in the decimal number system. (See <u>Advanced Topic 4.2</u> for more information.)

For this reason, the double type is not appropriate for financial calculations. In this book, we will continue to use double values for bank balances and other financial quantities so that we keep our programs as simple as possible. However, professional programs need to use the BigDecimal type for this purpose—see Advanced Topic 4.1.

135

136

In Java, it is legal to assign an integer value to a floating-point variable:

```
int dollars = 100;
double balance = dollars; // OK
```

But the opposite assignment is an error: You cannot assign a floating-point expression to an integer variable.

```
double balance = 13.75;
int dollars = balance; // Error
```

To overcome this problem, you can convert the floating-point value to an integer with a cast:

```
int dollars = (int) balance;
```

The cast (int) converts the floating-point value balance to an integer by discarding the fractional part. For example, if balance is 13.75, then dollars is set to 13.

```
You use a cast (typeName) to convert a value to a different type.
```

The cast tells the compiler that you agree to *information loss*, in this case, to the loss of the fractional part. You can also cast to other types, such as (float) or (byte).

If you want to round a floating-point number to the nearest whole number, use the Math.round method. This method returns a long integer, because large floating-point numbers cannot be stored in an int.

Use the Math.round method to round a floating-point number to the nearest integer.

```
long rounded = Math.round(balance);
```

If balance is 13.75, then rounded is set to 14.

#### SYNTAX 4.1 Cast

(typeName) expression

#### Example:

```
(int) (balance * 100)
```

#### Purpose:

To convert an expression to a different type

#### SELF CHECK

- 1. Which are the most commonly used number types in Java?
- 2. When does the cast (long) x yield a different result from the call Math.round(x)?
- 3. How do you round the double value x to the nearest int value, assuming that you know that it is less than  $2 \cdot 10^9$ ?

136

137

# ADVANCED TOPIC 4.1: Big Numbers

If you want to compute with really large numbers, you can use big number objects. Big number objects are objects of the <code>BigInteger</code> and <code>BigDecimal</code> classes in the <code>java.math</code> package. Unlike the number types such as <code>int</code> or <code>double</code>, big number objects have essentially no limits on their size and precision. However, computations with big number objects are much slower than those that involve number types. Perhaps more importantly, you can't use the familiar arithmetic operators such as (+ - \*) with them. Instead, you have to use methods called <code>add</code>, <code>subtract</code>, and <code>multiply</code>. Here is an example of how to create two big integers and how to multiply them.

```
BigInteger a = new BigInteger("1234567890");
BigInteger b = new BigInteger("9876543210");
BigInteger c = a.multiply(b);
System.out.println(c); // Prints 12193263111263526900
```

The BigDecimal type carries out floating-point computation without roundoff errors. For example,

```
BigDecimal d = new BigDecimal("4.35");
BigDecimal e = new BigDecimal ("100");
BigDecimal f = d.multiply(e);
System.out.println(f); // Prints 435.00
```

# ADVANCED TOPIC 4.2: Binary Numbers

You are familiar with decimal numbers, which use the digits 0, 1, 2, ..., 9. Each digit has a place value of 1, 10,  $100 = 10^2$ ,  $1000 = 10^3$ , and so on. For example,

$$435 = 4 \cdot 10^2 + 3 \cdot 10^1 + 5 \cdot 10^0$$

Fractional digits have place values with negative powers of ten:  $0.1 = 10^{1}$ ,  $0.01 = 10^{-2}$ , and so on. For example,

$$4.35 = 4 \cdot 10^{0} + 3 \cdot 10^{-1} + 5 \cdot 10^{-2}$$

Computers use binary numbers instead, which have just two digits (0 and 1) and place values that are powers of 2. Binary numbers are easier for computers to manipulate, because it is easier to build logic circuits that differentiate between "off" and "on" than it is to build circuits that can accurately tell ten different voltage levels apart.

It is easy to transform a binary number into a decimal number. Just compute the powers of two that correspond to ones in the binary number. For example,

1101 binary = 
$$1 \cdot 2^3 + 1 \cdot 2^2 + 0 \cdot 2^1 + 1 \cdot 2^0 = 8 + 4 + 1 = 13$$

Fractional binary numbers use negative powers of two. For example,

1.101 binary = 
$$1 \cdot 2^{0} + 1 \cdot 2^{-1} + 0 \cdot 2^{-2} + 1 \cdot 2^{-3} = 1 + 0.5 + 0.125 = 1.625$$

138

Converting decimal numbers to binary numbers is a little trickier. Here is an algorithm that converts a decimal integer into its binary equivalent: Keep dividing the integer by 2, keeping track of the remainders. Stop when the number is 0. Then write the remainders as a binary number, starting with the last one. For example,

```
100 \div 2 = 50 remainder 0

50 \div 2 = 25 remainder 0

25 \div 2 = 12 remainder 1

12 \div 2 = 6 remainder 0

6 \div 2 = 3 remainder 0

3 \div 2 = 1 remainder 1

1 \div 2 = 0 remainder 1
```

Therefore, 100 in decimal is 1100100 in binary.

To convert a fractional number <1 to its binary format, keep multiplying by 2. If the result is >1, subtract 1. Stop when the number is 0. Then use the digits before the decimal points as the binary digits of the fractional part, starting with the first one. For example,

$$0.35 \cdot 2 = 0.7$$

$$0.7 \cdot 2 = 1.4$$

$$0.4 \cdot 2 = 0.8$$

$$0.8 \cdot 2 = 1.6$$

$$0.6 \cdot 2 = 1.2$$

$$0.2 \cdot 2 = 0.4$$

Here the pattern repeats. That is, the binary representation of 0.35 is 0.01 0110 0110 0110 ...

To convert any floating-point number into binary, convert the whole part and the fractional part separately. For example, 4.35 is 100.01 0110 0110 0110 ... in binary.

You don't actually need to know about binary numbers to program in Java, but at times it can be helpful to understand a little about them. For example, knowing that an int is represented as a 32-bit binary number explains why the largest integer

that you can represent in Java is  $0111\ 1111\ 1111\ 1111\ 1111\ 1111\ 1111\ 1111$  linary = 2,147,483,647 decimal. (The first bit is the sign bit. It is off for positive values.)

To convert an integer into its binary representation, you can use the static toString method of the Integer class. The call Integer.toString(n, 2) returns a string with the binary digits of the integer n. Conversely, you can convert a string containing binary digits into an integer with the call Integer.parseInt(digitString, 2). In both of these method calls, the second parameter denotes the base of the number system. It can be any number between 0 and 36. You can use these two methods to convert between decimal and binary integers. However, the Java library has no convenient method to do the same for floatingpoint numbers.

Now you can see why we had to fight with a roundoff error when computing 100 times 4.35. If you actually carry out the long multiplication, you get:

```
138
139
```

```
1 1 0 0 1 0 0 * 1 0 0.0 1 0 1 1 0 0 1 1 0 0 1 1 0

...
1 0 0.0 1 0 1 1 0 0 1 1 0 0 1 1 0 ...
1 0 0.0 1 0 1 1 0 0 1 1 0 0 1 1 ...

0
1 0 0.0 1 0 1 1 1 0 0 1 1 0 ...

1 1 0 1 1 0 0 1 0.1 1 1 1 1 1 1 1 ...
```

That is, the result is 434, followed by an infinite number of 1s. The fractional part of the product is the binary equivalent of an infinite decimal fraction 0.999999 ..., which is equal to 1. But the CPU can store only a finite number of 1s, and it discards some of them when converting the result to a decimal number.

#### RANDOM FACT 4.1: The Pentium Floating-Point Bug

In 1994, Intel Corporation released what was then its most powerful processor, the first of the Pentium series. Unlike previous generations of Intel's processors, the Pentium had a very fast floating-point unit. Intel's goal was to compete

aggressively with the makers of higher-end processors for engineering workstations. The Pentium was an immediate success.

In the summer of 1994, Dr. Thomas Nicely of Lynchburg College in Virginia ran an extensive set of computations to analyze the sums of reciprocals of certain sequences of prime numbers. The results were not always what his theory predicted, even after he took into account the inevitable roundoff errors. Then Dr. Nicely noted that the same program did produce the correct results when run on the slower 486 processor, which preceded the Pentium in Intel's lineup. This should not have happened. The optimal roundoff behavior of floating-point calculations had been standardized by the Institute of Electrical and Electronics Engineers (IEEE), and Intel claimed to adhere to the IEEE standard in both the 486 and the Pentium processors. Upon further checking, Dr. Nicely discovered that indeed there was a very small set of numbers for which the product of two numbers was computed differently on the two processors. For example,

$$4,195,835 = ((4,195,835 / 3,145,727) \times 3,145,727)$$

is mathematically equal to 0, and it did compute as 0 on a 486 processor. On a Pentium processor, however, the result was 256.

As it turned out, Intel had independently discovered the bug in its testing and had started to produce chips that fixed it. (Subsequent versions of the Pentium, such as the Pentium III and IV, are free of the problem.) The bug was caused by an error in a table that was used to speed up the floating-point multiplication algorithm of the processor. Intel determined that the problem was exceedingly rare. They claimed that under normal use a typical consumer would only notice the problem once every 27,000 years. Unfortunately for Intel, Dr. Nicely had not been a normal user.

139 140

Now Intel had a real problem on its hands. It figured that replacing all the Pentium processors that it had already sold would cost it a great deal of money. Intel already had more orders for the chip than it could produce, and it would be particularly galling to have to give out the scarce chips as free replacements instead of selling them. Intel's management decided to punt on the issue and initially offered to replace the processors only for those customers who could prove that their work required absolute precision in mathematical calculations. Naturally, that did not go over well with the hundreds of thousands of customers who had paid retail prices of \$700 and more for a Pentium chip and did not want to

live with the nagging feeling that perhaps, one day, their income tax program would produce a faulty return.

Ultimately, Intel had to cave in to public demand and replaced all defective chips, at a cost of about 475 million dollars.

What do you think? Intel claims that the probability of the bug occurring in any calculation is extremely small—smaller than many chances you take every day, such as driving to work in an automobile. Indeed, many users had used their Pentium computers for many months without reporting any ill effects, and the computations that Professor Nicely was doing are hardly examples of typical user needs. As a result of its public relations blunder, Intel ended up paying a large amount of money. Undoubtedly, some of that money was added to chip prices and thus actually paid by Intel's customers. Also, a large number of processors, whose manufacture consumed energy and caused some environmental impact, were destroyed without benefiting anyone. Could Intel have been justified in wanting to replace only the processors of those users who could reasonably be expected to suffer an impact from the problem?

Suppose that, instead of stonewalling, Intel had offered you the choice of a free replacement processor or a \$200 rebate. What would you have done? Would you have replaced your faulty chip, or would you have taken your chances and pocketed the money?

#### 4.2 Constants

In many programs, you need to use numerical *constants*—values that do not change and that have a special significance for a computation.

A typical example for the use of constants is a computation that involves coin values, such as the following:

Most of the code is self-documenting. However, the four numeric quantities, 0.25, 0.1, 0.05, and 0.01 are included in the arithmetic expression without any explanation. Of course, in this case, you know that the value of a nickel is five cents, which

explains the 0.05, and so on. However, the next person who needs to maintain this code may live in another country and may not know that a nickel is worth five cents.

Thus, it is a good idea to use symbolic names for all values, even those that appear obvious. Here is a clearer version of the computation of the total:

```
140
```

There is another improvement we can make. There is a difference between the nickels and nickelValue variables. The nickels variable can truly vary over the life of the program, as we calculate different payments. But nickelValue is always 0.05.

```
A final variable is a constant. Once its value has been set, it cannot be changed.
```

In Java, constants are identified with the keyword final. A variable tagged as final can never change after it has been set. If you try to change the value of a final variable, the compiler will report an error and your program will not compile.

Many programmers use all-uppercase names for constants (final variables), such as NICKEL\_VALUE. That way, it is easy to distinguish between variables (with mostly lowercase letters) and constants. We will follow this convention in this book. However, this rule is a matter of good style, not a requirement of the Java language. The compiler will not complain if you give a final variable a name with lowercase letters.

```
Use named constants to make your programs easier to read and maintain.
```

Here is an improved version of the code that computes the value of a payment.

```
final double QUARTER_VALUE = 0.25;
final double DIME_VALUE = 0.1;
final double NICKEL VALUE = 0.05;
```

Frequently, constant values are needed in several methods. Then you should declare them together with the instance fields of a class and tag them as static and final. As before, final indicates that the value is a constant. The static keyword means that the constant belongs to the class—this is explained in greater detail in Chapter 8.)

142

141

We declared the constants as public. There is no danger in doing this because constants cannot be modified. Methods of other classes can access a public constant by first specifying the name of the class in which it is defined, then a period, then the name of the constant, such as CashRegister.NICKEL VALUE.

The Math class from the standard library defines a couple of useful constants:

You can refer to these constants as Math.PI and Math.E in any of your methods. For example,

```
double circumference = Math.PI * diameter;
```

The sample program at the end of this section puts constants to work. The program shows a refinement of the CashRegister class of How To 3.1. The public interface of that class has been modified in order to solve a common business problem.

Busy cashiers sometimes make mistakes totaling up coin values. Our Cash-Register class features a method whose inputs are the *coin counts*. For example, the call

```
register.enterPayment(1, 2, 1, 1, 4);
```

enters a payment consisting of one dollar, two quarters, one dime, one nickel, and four pennies. The enterPayment method figures out the total value of the payment, \$1.69. As you can see from the code listing, the method uses named constants for the coin values.

#### SYNTAX 4.2 Constant Definition

In a method:

final typeName variableName = expression;

In a class:

accessSpecifier static final typeName variableName = expression;

#### Example:

```
final double NICKEL_VALUE = 0.05;
public static final double LITERS_PER_GALLON =
3.785;
```

#### **Purpose:**

To define a constant in a method or a class

14.

```
143
```

```
ch04/cashregister/CashRegister.java
           /**
       1
       2

4 public class CashRegisterTester

public static void main(String[] args)

CashRegister register = new

CashRegister();

```
10
                  register.recordPurchase(0.75);
 11
                  register.recordPurchase(1.50);
12
                  register.enterPayment(2, 0, 5, 0,
0);
13
                 System.out.print("Change: ");
14
                  System.out.println(register.giveChange()
15
                 System.out.println("Expected:
0.25'');
16
17
                 register.recordPurchase(2.25);
18
                 register.recordPurchase(19.25);
19
                 register.enterPayment(23, 2, 0,
(0, 0);
20
                 System.out.print("Change:");
21
                  System.out.println(register.giveChange()
2.2
                 System.out.println("Expected: 2.0");
23
          }
24
```

# Output

Change: 0.25 Expected: 0.25 Change: 2.0 Expected: 2.0

#### SELF CHECK

4. What is the difference between the following two statements?

```
final double CM_PER_INCH = 2.54;
and
public static final double CM_PER_INCH = 2.54;
```

5. What is wrong with the following statement?

```
double circumference = 3.14 * diameter;
```

#### QUALITY TIP 4.1: Do Not Use Magic Numbers

A magic number is a numeric constant that appears in your code without explanation. For example, consider the following scary example that actually occurs in the Java library source:

```
h = 31 * h + ch;
```

Why 31? The number of days in January? One less than the number of bits in an integer? Actually, this code computes a "hash code" from a string—a number that is derived from the characters in such a way that different strings are likely to yield different hash codes. The value 31 turns out to scramble the character values nicely.

A better solution is to use a named constant:

```
final int HASH_MULTIPLIER = 31;
h = HASH_MULTIPLIER * h + ch;
```

You should never use magic numbers in your code. Any number that is not completely self-explanatory should be declared as a named constant. Even the most reasonable cosmic constant is going to change one day. You think there are 365 days in a year? Your customers on Mars are going to be pretty unhappy about your silly prejudice. Make a constant

```
final int DAYS_PER_YEAR = 365;
```

By the way, the device

```
final int THREE HUNDRED AND SIXTY FIVE = 365;
```

is counterproductive and frowned upon.

# **QUALITY TIP 4.2: Choose Descriptive Variable Names**

In algebra, variable names are usually just one letter long, such as p or A, maybe with a subscript such as  $p_1$ . You might be tempted to save yourself a lot of typing by using short variable names in your Java programs:

```
payment = d + q * QV + di * DIV + n * NV + p * PV;
```

Compare this with the following statement:

The advantage is obvious. Reading dollars is a lot less trouble than reading d and then figuring out that it must mean "dollars".

In practical programming, descriptive variable names are particularly important when programs are written by more than one person. It may be obvious to you that d stands for dollars, but is it obvious to the person who needs to update your code years later, long after you were promoted (or laid off)? For that matter, will you remember yourself what d means when you look at the code six months from now?

145

146

# 4.3 Assignment, Increment, and Decrement

The = operator is called the assignment operator. On the left, you need a variable name. The right-hand side can be a single value or an expression. The assignment operator sets the variable to the given value. So far, that's straightforward. But now let's look at a more interesting use of the assignment operator. Consider the statement

```
items = items + 1;
```

It means, "Compute the value of the expression items + 1, and place the result again into the variable items." (See <u>Figure 1</u>.) The net effect of executing this statement is to increment items by 1. For example, if items was 3 before execution of the statement, it is set to 4 afterwards. (This statement would be useful if the cash register kept track of the number of purchased items.)

The = sign does *not* mean that the left-hand side is equal to the right-hand side. Instead, it is an instruction to copy the right-hand-side value into the left-hand-side variable. You should not confuse this assignment operation with the = relation used in algebra to denote equality. The assignment operator is an instruction to do something, namely place a value into a variable. The mathematical equality states the fact that two values are equal. Of course, in mathematics it would make no sense to write that i = i + 1; no integer can equal itself plus 1.

The concepts of assignment and equality have no relationship with each other, and it is a bit unfortunate that the Java language (following C and C++) uses = to denote assignment. Other programming languages use a symbol such as - or :=, which avoids the confusion.

Assignment to a variable is not the same as mathematical equality.

The increment operation is so common when writing programs that there is a special shorthand for it, namely

items++;

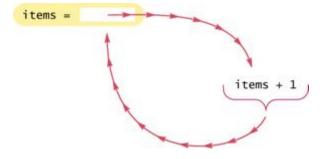

The ++ and -- operators increment and decrement a variable.

This statement also adds 1 to items. However, it is easier to type and read than the explicit assignment statement. As you might have guessed, there is also a decrement operator --. The statement

items--;

subtracts 1 from items.

#### Figure 1

Incrementing a Variable

146

147

#### SELF CHECK

**6.** What is the meaning of the following statement?

```
balance = balance + amount;

7. What is the value of n after the following sequence of statements?

n--;
n++;
n--;
```

# PRODUCTIVITY HINT 4.1: Avoid Unstable Layout

Arrange program code and comments so that the program is easy to read. For example, do not cram all statements on a single line, and make sure that braces { } line up.

However, be careful when you embark on beautification efforts. Some programmers like to line up the = signs in a series of assignments, like this:

```
nickels = 0;
dimes = 0;
quarters = 0;
```

This looks very neat, but the layout is not stable. Suppose you add a line like the one at the bottom of this:

```
nickels = 0;
dimes = 0;
quarters = 0;
halfDollars = 0;
```

Oops, now the = signs no longer line up, and you have the extra work of lining them up again.

Here is another example. Some programmers like to put a column of asterisks (\*) in documentation comments, like this:

```
/**
  * Computes the change due and resets the cash
register for the
  * next customer.
  * @return the change due to the customer
  */
```

It looks pretty, but it is tedious to rearrange the asterisks when editing comments.

You may not care about these issues. Perhaps you plan to beautify your program just before it is finished, when you are about to turn in your homework. That is not a particularly useful approach. In practice, programs are never finished. They are continuously improved and updated. It is better to develop the habit of laying out your programs well from the start and keeping them legible at all times. Therefore, it is a good idea to avoid layout schemes that are hard to maintain.

147

148

# ADVANCED TOPIC 4.3: Combining Assignment and Arithmetic

In Java you can combine arithmetic and assignment. For example, the instruction

```
balance += amount;
```

is a shortcut for

```
balance = balance + amount;
```

Similarly,

```
items *= 2;
```

is another way of writing

```
items = items * 2;
```

Many programmers find this a convenient shortcut. If you like it, go ahead and use it in your own code. For simplicity, we won't use it in this book.

# 4.4 Arithmetic Operations and Mathematical Functions

You already saw how to add, subtract, and multiply values. Division is indicated with a /, not a fraction bar. For example,

$$\frac{a+b}{2}$$

becomes

$$(a + b) / 2$$

Parentheses are used just as in algebra: to indicate in which order the subexpressions should be computed. For example, in the expression (a + b) / 2, the sum a + b is computed first, and then the sum is divided by 2. In contrast, in the expression

$$a + b / 2$$

only b is divided by 2, and then the sum of a and b / 2 is formed. Just as in regular algebraic notation, multiplication and division bind more strongly than addition and subtraction. For example, in the expression a + b / 2, the / is carried out first, even though the + operation occurs farther to the left.

Division works as you would expect, as long as at least one of the numbers involved is a floating-point number. That is,

If both arguments of the / operator are integers, the result is an integer and the remainder is discarded.

148 149

all yield 1.75. However, if both numbers are integers, then the result of the division is always an integer, with the remainder discarded. That is,

evaluates to 1, because 7 divided by 4 is 1 with a remainder of 3 (which is discarded). This can be a source of subtle programming errors—see Common Error 4.1.

If you are interested only in the remainder of an integer division, use the % operator:

The % operator computes the remainder of a division.

is 3, the remainder of the integer division of 7 by 4. The % symbol has no analog in algebra. It was chosen because it looks similar to /, and the remainder operation is related to division.

Here is a typical use for the integer / and % operations. Suppose you want to know how much change a cash register should give, using separate values for dollars and cents. You can compute the value as an integer, denominated in cents, and then compute the whole dollar amount and the remaining change:

For example, if total is 243, then dollars is set to 2 and cents to 43.

To compute  $x^n$ , you write Math.pow(x, n). However, to compute  $x^2$  it is significantly more efficient simply to compute  $x \times x$ .

The Math class contains methods sqrt and pow to compute square roots and powers.

To take the square root of a number, you use the Math.sqrt method. For example,  $\sqrt{x}$  is written as Math.sqrt(x).

In algebra, you use fractions, superscripts for exponents, and radical signs for roots to arrange expressions in a compact two-dimensional form. In Java, you have to write all expressions in a linear arrangement. For example, the subexpression

$$\frac{-b + \sqrt{b^2 - 4ac}}{2a}$$

of the quadratic formula becomes

$$(-b + Math.sqrt(b * b - 4 * a * c)) / (2 * a)$$

150

<u>Figure 2</u> shows how to analyze such an expression. With complicated expressions like these, it is not always easy to keep the parentheses () matched—see <u>Common Error 4.2</u>.

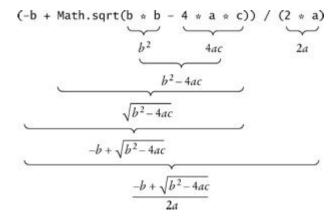

<u>Table 2</u> shows additional methods of the Math class. Inputs and outputs are floating-point numbers.

**Table 2 Mathematical Methods** 

Function	Returns	
Math.sqrt(x)	Square root of $x (\ge 0)$	
Math.pow(x, y)	$x^{y}$ (x > 0, or x = 0 and y > 0, or x < 0 and y is an integer)	
Math.sin(x)	Sine of x (x in radians)	
Math.cos(x)	Cosine of x	
Math.tan(x)	Tangent of x	
Math.asin(x)	Arc sine $(\sin^{-1} x \in [-\pi/2, \pi/2], x \in [-1, 1])$	
Math.acos(x)	Arc cosine $(\cos^{-1} x \in [0, \pi], x \in [-1, 1])$	
Math.atan(x)	Arc tangent (tan <sup>-1</sup> $x \in [-\pi/2, \pi/2]$ )	
Math.atan2(y, x)	Arc tangent (tan <sup>-1</sup> $y/x \in [-\pi, \pi]$ ), $x$ may be 0	
Math.toRadians(x)	Convert x degrees to radians (i.e., returns $x \cdot \pi/180$ )	
Math.toDegrees(x)	Convert $x$ radians to degrees (i.e., returns $x$ · 180/ $\pi$ )	
Math.exp(x)	e <sup>x</sup>	
Math.log(x)	Natural log $(ln(x), x > 0)$	
Math.round(x)	Closest integer to x (as a long)	
Math.ceil(x)	Smallest integer ≥x (as a double)	
Math.floor(x)	Largest integer ≤x (as a double)	
Math.abs(x)	Absolute value  x	
Math.max(x, y)	The larger of x and y	
Math.min(x, y)	The smaller of x and y	

151

Figure 2

Analyzing an Expression

#### SELF CHECK

- **8.** What is the value of 1729 / 100? Of 1729 % 100?
- 9. Why doesn't the following statement compute the average of s1, s2, and s3?

```
double average = s1 + s2 + s3 / 3; // Error
```

10. What is the value of Math.sqrt (Math.pow(x, 2) + Math.pow(y, 2)) in mathematical notation?

# COMMON ERROR 4.1: Integer Division

It is unfortunate that Java uses the same symbol, namely /, for both integer and floating-point division. These are really quite different operations. It is a common error to use integer division by accident. Consider this program segment that computes the average of three integers.

```
int s1 = 5; // Score of test 1
int s2 = 6; // Score of test 2
int s3 = 3; // Score of test 3
double average = (s1 + s2 + s3) / 3; // Error
```

```
System.out.print("Your average score is ");
System.out.println(average);
```

What could be wrong with that? Of course, the average of s1, s2, and s3 is

$$\frac{s_1 + s_2 + s_3}{3}$$

Here, however, the / does not mean division in the mathematical sense. It denotes integer division, because the values s1 + s2 + s3 and 3 are both integers. For example, if the scores add up to 14, the average is computed to be 4, the result of the integer division of 14 by 3.

151 152

That integer 4 is then moved into the floating-point variable average. The remedy is to make either the numerator or denominator into a floating-point number:

```
double total = s1 + s2 + s3;
double average = total / 3;
```

or

double average = (s1 + s2 + s3) / 3.0;

#### COMMON ERROR 4.2: Unbalanced Parentheses

Consider the expression

```
1.5 * ((-(b - Math.sqrt(b * b - 4 * a * c)) / (2 * a))
```

What is wrong with it? Count the parentheses. There are five opening parentheses ( and four closing parentheses ). The parentheses are unbalanced. This kind of typing error is very common with complicated expressions. Now consider this expression.

```
1.5 * (Math.sqrt(b * b - 4 * a * c))) - ((b / 2 * a))
```

This expression has five opening parentheses ( and five closing parentheses ), but it is still not correct. In the middle of the expression,

```
1.5 * (Math.sqrt(b * b - 4 * a * c))) - ((b / (2 * a))
```

there are only two opening parentheses (but three closing parentheses), which is an error. In the middle of an expression, the count of opening parentheses must be greater than or equal to the count of closing parentheses, and at the end of the expression the two counts must be the same.

Here is a simple trick to make the counting easier without using pencil and paper. It is difficult for the brain to keep two counts simultaneously, so keep only one count when scanning the expression. Start with 1 at the first opening parenthesis; add 1 whenever you see an opening parenthesis; subtract 1 whenever you see a closing parenthesis. Say the numbers aloud as you scan the expression. If the count ever drops below zero, or if it is not zero at the end, the parentheses are unbalanced. For example, when scanning the previous expression, you would mutter

and you would find the error.

# QUALITY TIP 4.3: White Space

The compiler does not care whether you write your entire program onto a single line or place every symbol onto a separate line. The human reader, though, cares very much. You should use blank lines to group your code visually into sections. For example, you can signal to the reader that an output prompt and the corresponding input statement belong together by inserting a blank line before and after the group. You will find many examples in the source code listings in this book.

152

153

White space inside expressions is also important. It is easier to read

```
x1 = (-b + Math.sqrt(b * b - 4 * a * c)) / (2 * a);
than
x1 = (-b+Math.sqrt(b*b-4*a*c)) / (2*a);
```

```
Chapter 4 Fundamental Data Types
```

Simply put spaces around all operators + - \*/% =. However, don't put a space after a unary minus: a - used to negate a single quantity, as in -b. That way, it can be easily distinguished from a binary minus, as in a - b. Don't put spaces between a method name and the parentheses, but do put a space after every Java keyword. That makes it easy to see that the sqrt in Math.sqrt(x) is a method name, whereas the if in if (x > 0) ... is a keyword.

#### QUALITY TIP 4.4: Factor Out Common Code

Suppose you want to find both solutions of the quadratic equation  $ax^2 + bx + c = 0$ . The quadratic formula tells us that the solutions are

$$x_{1, 2} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

In Java, there is no analog to the  $\pm$  operation, which indicates how to obtain two solutions simultaneously. Both solutions must be computed separately:

```
x1 = (-b + Math.sqrt(b * b - 4 * a * c)) / (2 * a);

x2 = (-b - Math.sqrt(b * b - 4 * a * c)) / (2 * a);
```

This approach has two problems. First, the computation of Math.sqrt (b \* b - 4 \* a \* c) is carried out twice, which wastes time. Second, whenever the same code is replicated, the possibility of a typing error increases. The remedy is to factor out the common code:

```
double root = Math.sqrt(b * b - 4 * a * c);
x1 = (-b + root) / (2 * a);
x2 = (-b - root) / (2 * a);
```

You could go even further and factor out the computation of 2 \* a, but the gain from factoring out very simple computations is too small to warrant the effort.

#### 4.5 Calling Static Methods

In the preceding section, you encountered the Math class, which contains a collection of helpful methods for carrying out mathematical computations. These methods have a special form: they are static methods that do not operate on an object.

```
That is, you don't call
double x = 4;
double root = x.sqrt(); // Error
```

153 154

because, in Java, numbers are not objects, so you can never invoke a method on a number. Instead, you pass a number as an explicit parameter to a method, enclosing the number in parentheses after the method name. For example, the number value x can be a parameter of the Math.sqrt method: Math.sqrt(x).

This call makes it appear as if the sqrt method is applied to an object called Math, because Math precedes sqrt just as harrysChecking precedes getBalance in a method call harrysChecking.getBalance(). However, Math is a class, not an object. A method such as Math.round that does not operate on any object is called a *static* method. (The term "static" is a historical holdover from the C and C++ programming languages. It has nothing to do with the usual meaning of the word.) Static methods do not operate on objects, but they are still defined inside classes. You must specify the class to which the sqrt method belongs—hence the call is Math.sqrt(x).

A static method does not operate on an object.

How can you tell whether Math is a class or an object? All classes in the Java library start with an uppercase letter (such as System). Objects and methods start with a lowercase letter (such as out and println). (You can tell objects and methods apart because method calls are followed by parentheses.) Therefore, System.out.println() denotes a call of the println method on the out object inside the System class. On the other hand, Math.sqrt(x) denotes a call to the sqrt method inside the Math class. This use of upper- and lowercase letters is merely a convention, not a rule of the Java language. It is, however, a convention that the authors of the Java class libraries follow consistently. You should do the same in your programs. If you give names to objects or methods that start with uppercase letters, you will likely confuse your fellow programmers. Therefore, we strongly recommend that you follow the standard naming convention.

#### SYNTAX 4.3 Static Method Call

ClassName.methodName (parameters)

#### Example:

```
Math.sqrt(4)
```

#### Purpose:

To invoke a static method (a method that does not operate on an object) and supply its parameters

#### SELF CHECK

- 11. Why can't you call x.pow (y) to compute  $x^y$ ?
- 12. Is the call System.out.println(4) a static method call?

154

#### COMMON ERROR 4.3: Roundoff Errors

Roundoff errors are a fact of life when calculating with floating-point numbers. You probably have encountered this phenomenon yourself with manual calculations. If you calculate 1/3 to two decimal places, you get 0.33. Multiplying again by 3, you obtain 0.99, not 1.00.

In the processor hardware, numbers are represented in the binary number system, not in decimal. You still get roundoff errors when binary digits are lost. They just may crop up at different places than you might expect. Here is an example:

```
double f = 4.35;
int n = (int) (100 * f);
System.out.println(n); // Prints 434!
```

Of course, one hundred times 4.35 is 435, but the program prints 434.

Computers represent numbers in the binary system (see <u>Advanced Topic 4.2</u>). In the binary system, there is no exact representation for 4.35, just as there is no exact representation for 1/3 in the decimal system. The representation used by the computer is just a little less than 4.35, so 100 times that value is just a little less than 435. When a floating-point value is converted to an integer, the entire fractional part is discarded, even if it is almost 1. As a result, the integer 434 is

stored in n. Remedy: Use Math.round to convert floating-point numbers to integers. The round method returns the *closest* integer.

int n = (int) Math.round(100 \* f); // OK, n is 435

# How To 4.1: Carrying Out Computations

Many programming problems require that you use mathematical formulas to compute values. It is not always obvious how to turn a problem statement into a sequence of mathematical formulas and, ultimately, statements in the Java programming language.

**Step 1** Understand the problem: What are the inputs? What are the desired outputs?

For example, suppose you are asked to simulate a postage stamp vending machine. A customer inserts money into the vending machine. Then the customer pushes a "First class stamps" button. The vending machine gives out as many first-class stamps as the customer paid for. (A first-class stamp cost 39 cents at the time this book was written.) Finally, the customer pushes a "Penny stamps" button. The machine gives the change in penny (1-cent) stamps.

In this problem, there is one input:

• The amount of money the customer inserts

There are two desired outputs:

- The number of first-class stamps the machine returns
- The number of penny stamps the machine returns

**Step 2** Work out examples by hand.

This is a very important step. If you can't compute a couple of solutions by hand, it's unlikely that you'll be able to write a program that automates the computation.

155

Let's assume that a first-class stamp costs 39 cents and the customer inserts \$1.00. That's enough for two stamps (78 cents) but not enough for three stamps (\$1.17). Therefore, the machine returns two first-class stamps and 22 penny stamps.

**Step 3** Find mathematical equations that compute the answers.

Given an amount of money and the price of a first-class stamp, how can you compute how many first-class stamps can be purchased with the money? Clearly, the answer is related to the quotient

For example, suppose the customer paid \$1.00. Use a pocket calculator to compute the quotient:  $$1.00/$0.39 \approx 2.5641$ .

How do you get "2 stamps" out of 2.5641? It's the integer part. By discarding the fractional part, you get the number of whole stamps the customer has purchased.

In mathematical notation,

number of first-class stamps 
$$= \lfloor \frac{\text{money}}{\text{price of first-class stamp}} \rfloor$$

where  $\lfloor x \rfloor$  denotes the largest integer  $\leq x$ . That function is sometimes called the "floor function".

You now know how to compute the number of stamps that are given out when the customer pushes the "First-class stamps" button. When the customer gets the stamps, the amount of money is reduced by the value of the stamps purchased. For example, if the customer gets two stamps, the remaining money is \$0.22—the difference between \$1.00 and 2 c \$0.39. Here is the general formula:

remaining money = money - number of first-class stamps · price of first-class stamp

How many penny stamps does the remaining money buy? That's easy. If \$0.22 is left, the customer gets 22 stamps. In general, the number of penny stamps is number of penny stamps = 100 · remaining money

**Step 4** Turn the mathematical equations into Java statements.

In Java, you can compute the integer part of a nonnegative floating-point value by applying an (int) cast. Therefore, you can compute the number of first-class stamps with the following statement:

```
firstClassStamps = (int) (money /
     FIRST CLASS STAMP PRICE);
     money = money - firstClassStamps *
     FIRST CLASS STAMP PRICE;
Finally, the number of penny stamps is
     pennyStamps = 100 * money;
That's not quite right, though. The value of pennyStamps should be an integer,
but the right-hand side is a floating-point number. Therefore, the correct statement
is
     pennyStamps = (int) Math.round(100 * money);
Step 5 Build a class that carries out your computations.
How To 3.1 explains how to develop a class by finding methods and instance
variables. In our case, we can find three methods:
                                                                         156
                                                                         157
    void insert(double amount)
    int giveFirstClassStamps()
     int givePennyStamps()
The state of a vending machine can be described by the amount of money that the
customer has available for purchases. Therefore, we supply one instance variable,
money.
Here is the implementation:
     public class StampMachine
            public StampMachine()
                    money = 0;
            public void insert(double amount)
                    money = money + amount;
```

public int giveFirstClassStamps()

#### Step 6 Test your class.

Run a test program (or use an integrated environment such as BlueJ) to verify that the values that your class computes are the same values that you computed by hand. In our example, try the statements

```
StampMachine machine = new StampMachine();
   machine.insert(1);
   System.out.print("First class stamps: ");
   System.out.println(machi
   ne.giveFirstClassStamps());
   System.out.println("Expected: 2");
   System.out.println("Penny stamps: ");
   System.out.println (machine.givePennyStamps());
   System.out.println("Expected: 22);

Check that the result is

First class stamps: 2
   Expected: 2
   Penny stamps: 22
   Expected: 22
```

# 4.6 Strings

Next to numbers, strings are the most important data type that most programs use. A string is a sequence of characters, such as "Hello, World!". In Java, strings are enclosed in quotation marks, which are not themselves part of the string. Note that, unlike numbers, strings are objects. (You can tell that String is a class name because it starts with an uppercase letter. The primitive types int and double start with lowercase letters.)

The number of characters in a string is called the length of the string. For example, the length of "Hello, World!" is 13. You can compute the length of a string with the length method.

A string is a sequence of characters. Strings are objects of the String class.

```
int n = message.length();
```

A string of length zero, containing no characters, is called the empty string and is written as "".

Use the + operator to put strings together to form a longer string.

```
String name = "Dave";
String message = "Hello, " + name;
```

The + operator concatenates two strings, provided one of the expressions, either to the left or the right of a + operator, is a string. The other one is automatically forced to become a string as well, and both strings are concatenated.

Strings can be concatenated, that is, put end to end to yield a new longer string. String concatenation is denoted by the + operator.

For example, consider this code:

```
String a = "Agent";
int n = 7;
String bond = a + n;
```

Because a is a string, n is converted from the integer 7 to the string "7". Then the two strings "Agent" and "7" are concatenated to form the string "Agent7".

Whenever one of the arguments of the + operator is a string, the other argument is converted to a string.

This concatenation is very useful to reduce the number of System, out.print instructions. For example, you can combine

```
System.out.print("The total is ");
System.out.println(total);
```

to the single call

```
System.out.println("The total is " + total);
```

The concatenation "The total is " + total computes a single string that consists of the string "The total is ", followed by the string equivalent of the number total.

Sometimes you have a string that contains a number, usually from user input. For example, suppose that the string variable input has the value "19". To get the integer value 19, you use the static parseInt method of the Integer class.

```
int count = Integer.parseInt(input);
    // count is the integer 19
```

158 159

Figure 3

**String Positions** 

To convert a string containing floating-point digits to its floating-point value, use the static parseDouble method of the Double class. For example, suppose input is the string "3.95".

If a string contains the digits of a number, you use the Integer.parseInt or Double.parseDouble method to obtain the number value.

```
double price = Double.parseDouble(input);
    // price is the floating-point number 3.95
```

However, if the string contains spaces or other characters that cannot occur inside numbers, an error occurs. For now, we will always assume that user input does not contain invalid characters.

The substring method computes substrings of a string. The call

```
Use the substring method to extract a part of a string.
```

```
s.substring(start, pastEnd)
```

returns a string that is made up of the characters in the string s, starting at position start, and containing all characters up to, but not including, the position pastEnd. Here is an example:

```
String greeting = "Hello, World!";
String sub = greeting.substring(0, 5); // sub is
"Hello"
```

The substring operation makes a string that consists of five characters taken from the string greeting. A curious aspect of the substring operation is the numbering of the starting and ending positions. The first string position is labeled 0, the second one 1, and so on. For example, <u>Figure 3</u> shows the position numbers in the greeting string.

```
String positions are counted starting with 0.
```

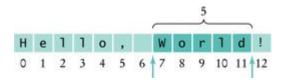

The position number of the last character (12 for the string "Hello, World!") is always 1 less than the length of the string.

Let us figure out how to extract the substring "World". Count characters starting at 0, not 1. You find that W, the eighth character, has position number 7. The first

character that you don't want, !, is the character at position 12 (see <u>Figure 4</u>). Therefore, the appropriate substring command is

```
String sub2 = greeting.substring(7, 12);
```

# Figure 4

#### Extracting a Substring

It is curious that you must specify the position of the first character that you do want and then the first character that you don't want. There is one advantage to this setup. You can easily compute the length of the substring: It is pastEnd - start. For example, the string "World" has length 12 - 7625.

159 160

If you omit the second parameter of the substring method, then all characters from the starting position to the end of the string are copied. For example,

```
String tail = greeting.substring(7); // Copies all characters from position 7 on sets tail to the string "World!".
```

If you supply an illegal string position (a negative number, or a value that is larger than the length of the string), then your program terminates with an error message.

In this section, we have made the assumption that each character in a string occupies a single position. Unfortunately, that assumption is not quite correct. If you process strings that contain characters from international alphabets or special symbols, some characters may occupy two positions—see <u>Advanced Topic 4.5</u>.

#### SELF CHECK

13. Assuming the String variable s holds the value "Agent", what is the effect of the assignments s = s + s.length()?

# PRODUCTIVITY HINT 4.2: Reading Exception Reports

You will often have programs that terminate and display an error message, such as

An amazing number of students simply give up at that point, saying "it didn't work", or "my program died", without ever reading the error message. Admittedly, the format of the exception report is not very friendly. But it is actually easy to decipher it.

When you have a close look at the error message, you will notice two pieces of useful information:

- 1. The name of the exception, such as StringIndexOutOfBoundsException
- 2. The line number of the code that contained the statement that caused the exception, such as Homework1.java:16

The name of the exception is always in the first line of the report, and it ends in Exception. If you get a StringIndexOutOfBoundsException, then there was a problem with accessing an invalid position in a string. That is useful information.

The line number of the offending code is a little harder to determine. The exception report contains the entire stack trace—that is, the names of all methods that were pending when the exception hit. The first line of the stack trace is the method that actually generated the exception. The last line of the stack trace is a line in main. Often, the exception was thrown by a method that is in the standard

160

library. Look for the first line in your code that appears in the exception report. For example, skip the line that refers to

```
java.lang.String.substring(String.java:1444)
```

The next line in our example mentions a line number in your code, Homework1.java. Once you have the line number in your code, open up the file, go to that line, and look at it! In the great majority of cases, knowing the name of the exception and the line that caused it make it completely obvious what went wrong, and you can easily fix your error.

# ADVANCED TOPIC 4.4: Escape Sequences

Suppose you want to display a string containing quotation marks, such as

```
Hello, "World"!
```

You can't use

```
System.out.println("Hello, "World"!");
```

As soon as the compiler reads "Hello,", it thinks the string is finished, and then it gets all confused about World followed by two quotation marks. A human would probably realize that the second and third quotation marks were supposed to be part of the string, but a compiler has a one-track mind. If a simple analysis of the input doesn't make sense to it, it just refuses to go on, and reports an error. Well, how do you then display quotation marks on the screen? You precede the quotation marks inside the string with a *backslash* character. Inside a string, the sequence \" denotes a literal quote, not the end of a string. The correct display statement is, therefore

```
System.out.println("Hello, \"World\"!");
```

The backslash character is used as an *escape* character; the character sequence \" is called an escape sequence. The backslash does not denote itself; instead, it is used to encode other characters that would otherwise be difficult to include in a string.

Now, what do you do if you actually want to print a backslash (for example, to specify a Windows file name)? You must enter two \ in a row, like this:

```
System.out.println("The secret message is in
C:\\Temp\\Secret.txt");
```

#### This statement prints

```
The secret message is in C:\Temp\Secret.txt
```

Another escape sequence occasionally used is \n, which denotes a *newline* or line feed character. Printing a newline character causes the start of a new line on the display. For example, the statement

```
System.out.print("*n**n***n");
```

prints the characters

\*

161 162

on three separate lines. Of course, you could have achieved the same effect with three separate calls to println.

Finally, escape sequences are useful for including international characters in a string. For example, suppose you want to print "All the way to San José!", with an accented letter (é). If you use a U.S. keyboard, you may not have a key to generate that letter. Java uses the *Unicode* encoding scheme to denote international characters. For example, the é character has Unicode encoding 00E9. You can include that character inside a string by writing \u, followed by its Unicode encoding:

```
System.out.println("All the way to San
Jos\u00E9!");
```

You can look up the codes for the U.S. English and Western European characters in Appendix B, and codes for thousands of characters in reference [1].

# ADVANCED TOPIC 4.5: Strings and the Char Type

Strings are sequences of Unicode characters (see <u>Random Fact 4.2</u>). Character constants look like string constants, except that character constants are delimited by single quotes: 'H' is a character, "H" is a string containing a single character.

You can use escape sequences (see <u>Advanced Topic 4.4</u>) inside character constants. For example, '\n' is the newline character, and '\u00E9' is the character é. You can find the values of the character constants that are used in Western European languages in Appendix B.

Characters have numeric values. For example, if you look at Appendix B, you can see that the character 'H' is actually encoded as the number 72.

When Java was first designed, each Unicode character was encoded as a two-byte quantity. The char type was intended to hold the code of a Unicode character. However, as of 2003, Unicode had grown so large that some characters needed to be encoded as pairs of char values. Thus, you can no longer think of a char value as a character. Technically speaking, a char value is a *code unit* in the UTF-16 encoding of Unicode. That encoding represents the most common characters as a single char value, and less common or *supplementary* characters as a pair of char values.

The charAt method of the String class returns a code unit from a string. As with the sub-string method, the positions in the string are counted starting at 0. For example, the statement

```
String greeting = "Hello";
char ch = greeting.charAt(0);
sets ch to the value 'H'.
```

However, if you use char variables, your programs may fail with some strings that contain international or symbolic characters. For example, the single character  $\mathbb{Z}$  (the mathematical symbol for the set of integers) is encoded by the two code units '\uDB835' and '\uDD6B'.

If you call charAt (0) on the string containing the single character  $\mathbb{Z}$  (that is, the string "\uDB35\uDD6B"), you only get the first half of a supplementary character.

Therefore, you should only use char values if you are absolutely sure that you won't need to encode supplementary characters.

# RANDOM FACT 4.2: International Alphabets

The English alphabet is pretty simple: upper- and lowercase a to z. Other European languages have accent marks and special characters. For example, German has three umlaut characters (ä, ö, ü) and a double-s character (ß). These are not optional frills; you couldn't write a page of German text without using these characters. German computer keyboards have keys for these characters (see A German Keyboard).

This poses a problem for computer users and designers. The American standard character encoding (called ASCII, for American Standard Code for Information Interchange) specifies 128 codes: 52 upper- and lowercase characters, 10 digits, 32 typographical symbols, and 34 control characters (such as space, newline, and 32 others for controlling printers and other devices). The umlaut and double-s are not among them. Some German data processing systems replace seldom-used ASCII characters with German letters: [ \ ] { | } ~ are replaced with Ä Ö Ü ä ö ü ß. Most people can live without those ASCII characters, but programmers using Java definitely cannot. Other encoding schemes take advantage of the fact that one byte can encode 256 different characters, but only 128 are standardized by ASCII. Unfortunately, there are multiple incompatible standards for using the remaining 128 characters, resulting in a certain amount of aggravation among e-mail correspondents in different European countries.

Many countries don't use the Roman script at all. Russian, Greek, Hebrew, Arabic, and Thai letters, to name just a few, have completely different shapes (see The Thai Alphabet). To complicate matters, scripts like Hebrew and Arabic are written from right to left instead of from left to right, and many of these scripts have characters that stack above or below other characters, as those marked with a dotted circle in The Thai Alphabet do in Thai. Each of these alphabets has between 30 and 100 letters, and the countries using them have established encoding standards for them.

The situation is much more dramatic in languages that use Chinese script: the Chinese dialects, Japanese, and Korean. The Chinese script is not alphabetic but ideographic—a character represents an idea or thing rather than a single sound. (See A Menu with Chinese Characters; can you identify the characters for soup,

chicken, and wonton?) Most words are made up of one, two, or three of these ideographic characters. Tens of thousands of ideographs are in active use, and China, Taiwan, Hong Kong, Japan, and Korea developed incompatible encoding standards for them.

The Thai Alphabet

The inconsistencies among character encodings have been a major nuisance for international electronic communication and for software manufacturers vying for a global market. Between 1988 and 1991 a consortium of hardware and software manufacturers developed a uniform encoding scheme called Unicode that is expressly designed to encode text in all written languages of the world (see reference [1]). In the first version of Unicode, about 39,000 characters were given codes, including 21,000 Chinese ideographs. A 2-byte code (which can encode

over 65,000 characters) was chosen. It was thought to leave ample space for expansion for esoteric scripts, such as Egyptian hieroglyphs and the ancient script used on the island of Java.

Java was one of the first programming languages to embrace Unicode. The primitive type char denotes a 2-byte Unicode character. (All Unicode characters can be stored in Java strings, but which ones can actually be displayed depends on your computer system.)

					•	

164

Unfortunately, in 2003, the inevitable happened. Another large batch of Chinese ideographs had to be added to Unicode, pushing it beyond the 16-bit limit. Now, some characters need to be encoded with a pair of char values.

# 4.7 Reading Input

The Java programs that you have made so far have constructed objects, called methods, printed results, and exited. They were not interactive and took no user input. In this section, you will learn one method for reading user input.

Use the Scanner class to read keyboard input in a console window.

Because output is sent to System.out, you might think that you use System.in for input. Unfortunately, it isn't quite that simple. When Java was first designed, not

much attention was given to reading keyboard input. It was assumed that all programmers would produce graphical user interfaces with text fields and menus. System.in was given a minimal set of features—it can only read one byte at a time. Finally, in Java version 5, a Scanner class was added that lets you read keyboard input in a convenient manner.

To construct a Scanner object, simply pass the System.in object to the Scanner constructor:

```
Scanner in = new Scanner(System.in);
```

You can create a scanner out of any input stream (such as a file), but you will usually want to use a scanner to read keyboard input from System.in.

Once you have a scanner, you use the nextInt or nextDouble methods to read the next integer or floating-point number.

```
System.out.print("Enter quantity: ");
int quantity = in.nextInt();
System.out.print("Enter price: ");
double price = in.nextDouble();
```

When the nextInt or nextDouble method is called, the program waits until the user types a number and hits the Enter key. You should always provide instructions for the user (such as "Enter quantity:") before calling a Scanner method. Such an instruction is called a *prompt*.

The nextLine method returns the next line of input (until the user hits the Enter key) as a String object. The next method returns the next *word*, terminated by any *white space*, that is, a space, the end of a line, or a tab.

```
System.out.print("Enter city: ");
String city = in.nextLine();
System.out.print("Enter state code: ");
String state = in.next();
```

Here, we use the nextLine method to read a city name that may consist of multiple words, such as San Francisco. We use the next method to read the state code (such as CA), which consists of a single word.

Here is an example of a class that takes user input. This class uses the CashRegister class and simulates a transaction in which a user purchases an item, pays for it, and receives change.

We call this class CashRegisterSimulator, not CashRegisterTester. We reserve the Tester suffix for classes whose sole purpose is to test other classes.

```
ch04/cashregister/CashRegisterSimulator.java
      1
         import java.util.Scanner;
      2
         /**
      3
           This program simulates a transaction in
    which a user pays for an item
             and receives change.
         */
      6
      7
              public class CashRegisterSimulator
      8
                     public static void main(String[]
      9
    args)
     10
     11
                           Scanner in = new
    Scanner(System.in);
     12
     13
                           CashRegister register = new
    CashRegister();
     14
     15
                           System.out.print("Enter
    price: ");
                           double price =
    in.nextDouble();
     17
                           register.recordPurchase(price);
     18
     19
                           System.out.print("Enter
    dollars: ");
     20
                           int dollars = in.nextInt();
     2.1
                           System.out.print("Enter
    quarters: ");
     22
                           int quarters = in.nextInt();
     23
                           System.out.print("Enter
    dimes: ");
                           int dimes = in.nextInt();
```

```
25
                       System.out.print("Enter
nickels: ");
26
                       int nickels = in.nextInt();
27
                       System.out.print("Enter
pennies: ");
2.8
                       int pennies = in.nextInt();
                       register.enterPayment (dollars,
quarters, dimes, nickels, pennies);
31
                       System.out.print("Your
change: ");
32
                       System.out.println(register.giveCha
33
               }
34
```

# Output Enter price: 7.55 Enter dollars: 10 Enter quarters: 2 Enter dimes: 1

Enter nickels: 0
Enter pennies: 0

Your change: 3.05

SELF CHECK

- 15. Why can't input be read directly from System.in?
- 16. Suppose in is a Scanner object that reads from System.in, and your program calls

```
String name = in.next();
```

What is the value of name if the user enters John Q. Public?

# ADVANCED TOPIC 4.6: Formatting Numbers

The default format for printing numbers is not always what you would like. For example, consider the following code segment:

```
double total = 3.50;
final double TAX RATE = 8.5; // Tax rate in percent
```

```
double tax = total * TAX_RATE / 100; // tax is 0.2975
System.out.println("Total: " + total);
System.out.println("Tax: " + tax);
```

The output is

```
Total: 3.5
Tax: 0.2975
```

You may prefer the numbers to be printed with two digits after the decimal point, like this:

```
Total: 3.50 Tax: 0.30
```

You can achieve this with the printf method of the PrintStream class. (Recall that System.out is an instance of PrintStream.) The first parameter of the printf method is a *format string* that shows how the output should be formatted. The format string contains characters that are simply printed, and *format specifiers*: codes that start with a % character and end with a letter that indicates the format type. There are quite a few formats—<u>Table 3</u> shows the most important ones. The remaining parameters of printf are the values to be formatted. For example,

```
System.out.printf("Total:%5.2f", total);
```

prints the string Total:, followed by a floating-point number with a *width* of 5 and a *precision* of 2. The width is the total number of characters to be printed: in our case, a space, the digit 3, a period, and two digits. If you increase the width, more spaces are added. The precision is the number of digits after the decimal point.

This simple use of printf is sufficient for most formatting needs. Once in a while, you may see a more complex example, such as this one:

```
System.out.printf("%-6s%5.2f%n", "Tax:", total);
```

Here, we have three format specifiers. The first one is %-6s. The s indicates a string. The hyphen is a *flag*, modifying the format. (See <u>Table 4</u> for the most common format flags. The flags immediately follow the % character.) The hyphen indicates left alignment. If the string to be formatted is shorter than the width, it is

167

placed to the left, and spaces are added to the right. (The default is right alignment, with spaces added to the left.) Thus, %-6s denotes a left-aligned string of width 6.

**Table 3 Format Types** 

Code	Туре	Example
d	Decimal integer	123
X	Hexadecimal integer	7B
0	Octal integer	173
f	Fixed floating-point	12.30
е	Exponential floating-point	1.23e+1
g	General floating-point (exponential	12.3
	notation used for very large or very	
	small values)	
S	String	Tax:
n	Platform-independent line end	

You have already seen \$5.2f: a floating-point number of width 5 and precision 2. The final specifier is \$n, indicating a platform-independent line end. In Windows, lines need to be terminated by *two* characters: a carriage return '\r' and a newline '\n'. In other operating systems, a '\n' suffices. The \$n format emits the appropriate line terminators.

Moreover, this call to printf has two parameters. You can supply any number of parameter values to the printf method. Of course, they must match the format specifiers in the format string.

**Table 4 Format Flags** 

Flag	Meaning	Example	
-	Left alignment	1.23 followed by spaces	
0	Show leading zeroes	001.23	
+	Show a plus sign for positive	+1.23	
	numbers		
(	Enclose negative numbers in	(1.23)	
	parentheses		
,	Show decimal separators	12,300	
^	Convert letters to uppercase	1.23E+1	

168 169

The format method of the String class is similar to the printf method. However, it returns a string instead of producing output. For example, the call

```
String message = String.format("Total:%5.2f",
    total);
sets the message variable to the string "Total: 3.50".
```

# ADVANCED TOPIC 4.7: Using Dialog Boxes for Input and Output

Most program users find the console window rather old-fashioned. The easiest alternative is to create a separate pop-up window for each input (see An Input Dialog Box).

Call the static showInputDialog method of the JOptionPane class, and supply the string that prompts the input from the user. For example,

```
String input = JOptionPane.showInputDialog("Enter
price:");
```

That method returns a String object. Of course, often you need the input as a number. Use the Integer.parseInt and Double.parseDouble methods to convert the string to a number:

```
double price = Double.parseDouble(input);
```

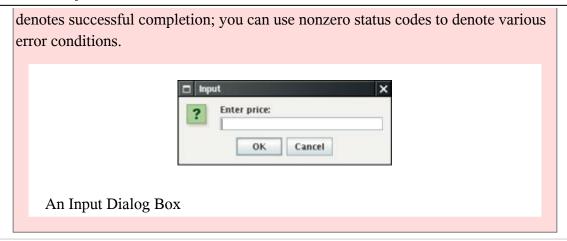

You can also display output in a dialog box:

```
JOptionPane.showMessageDialog(null, "Price: " +
price);
```

Finally, whenever you call the showInputDialog or showMessageDialog method in a program that does not show any other frame windows, you need to add a line

```
System.exit(0);
```

to the end of your main method. The showInputDialog method starts a user interface thread to handle user input. When the main method reaches the end, that thread is still running, and your program won't exit automatically. To force the program to exit, you need to call the exit method of the System class. The parameter of the exit method is the status code of the program. A code of 0

#### **CHAPTER SUMMARY**

- 1. Java has eight primitive types, including four integer types and two floating point types.
- 2. A numeric computation overflows if the result falls outside the range for the number type.
- 3. Rounding errors occur when an exact conversion between numbers is not possible.
- 4. You use a cast (typeName) to convert a value to a different type.
- 5. Use the Math.round method to round a floating-point number to the nearest integer.
- 6. A final variable is a constant. Once its value has been set, it cannot be changed.
- 7. Use named constants to make your programs easier to read and maintain.
- 8. Assignment to a variable is not the same as mathematical equality.
- 9. The ++ and -- operators increment and decrement a variable.
- 10. If both arguments of the / operator are integers, the result is an integer and the remainder is discarded.
- 11. The % operator computes the remainder of a division.

- 12. The Math class contains methods sqrt and pow to compute square roots and powers.
- 13. A static method does not operate on an object.
- 14. A string is a sequence of characters. Strings are objects of the String class.
- 15. Strings can be concatenated, that is, put end to end to yield a new longer string. String concatenation is denoted by the + operator.
- 16. Whenever one of the arguments of the + operator is a string, the other argument is converted to a string.
- 17. If a string contains the digits of a number, you use the Integer.parseInt or Double.parseDouble method to obtain the number value.
- 18. Use the substring method to extract a part of a string.
- 19. String positions are counted starting with 0.
- 20. Use the Scanner class to read keyboard input in a console window.

#### **REVIEW EXERCISES**

 $\star\star$  Exercise R4.1. Write the following mathematical expressions in Java.

$$s = s_0 + v_0 t + \frac{1}{2} g t^2$$

$$G = 4\pi^2 \frac{a^3}{p^2 (m_1 + m_2)}$$

$$FV = PV \cdot \left(1 + \frac{INT}{100}\right)^{YRS}$$

$$c = \sqrt{a^2 + b^2 - 2ab \cos \gamma}$$

171 172

★★ Exercise R4.2. Write the following Java expressions in mathematical notation.

- a. dm = m \* (Math.sqrt(1 + v / c) / (Math.sqrt(1 v / c) 1));
- **b.** volume = Math.PI \* r \* r \* h;
- c. volume = 4 \* Math.PI \* Math.pow(r, 3) / 3;
- **d.** p = Math.atan2(z, Math.sqrt(x \* x + y \* y));

★★★ Exercise R4.3. What is wrong with this version of the quadratic formula?

$$x1 = (-b - Math.sqrt(b * b - 4 * a * c)) / 2 * a;$$
  
 $x2 = (-b + Math.sqrt(b * b - 4 * a * c)) / 2 * a;$ 

- ★★ Exercise R4.4. Give an example of integer overflow. Would the same example work correctly if you used floating-point?
- ★★ Exercise R4.5. Give an example of a floating-point roundoff error. Would the same example work correctly if you used integers and switched to a sufficiently small unit, such as cents instead of dollars, so that the values don't have a fractional part?
- ★★ Exercise R4.6. Consider the following code:

```
CashRegister register = new CashRegister();
register.recordPurchase(19.93);
register.enterPayment(20, 0, 0, 0, 0);
System.out.print("Change: ");
System.out.println(register.giveChange());
```

The code segment prints the total as 0.07000000000000028. Explain why. Give a recommendation to improve the code so that users will not be confused.

 $\star$  Exercise R4.7. Let n be an integer and x a floating-point number. Explain the difference between

```
n = (int) x;
and
n = (int) Math.round(x);
```

 $\star\star\star$  Exercise R4.8. Let n be an integer and x a floating-point number.

Explain the difference between

```
n = (int) (x + 0.5);
and
n = (int) Math.round(x);
```

For what values of x do they give the same result? For what values of x do they give different results?

- ★ Exercise R4.9. Explain the differences between 2, 2.0, '2', "2", and "2.0".
- ★ Exercise R4.10. Explain what each of the following two program segments computes:

```
int x = 2;
int y = x + x;
and
String s = "2";
String t = s + s;
```

 $\star\star$  Exercise R4.11. True or false? (x is an int and s is a String)

```
a. Integer.parseInt("" + x) is the same as x
```

- **b.** "" + Integer.parseInt(s) is the same as s
- c. s.substring(0, s.length()) is the same as s
- ★★ Exercise R4.12. How do you get the first character of a string? The last character? How do you remove the first character? The last character?
- ★★★ Exercise R4.13. How do you get the last digit of an integer? The first digit? That is, if n is 23456, how do you find out that the first digit is 2 and the last digit is 6? Do not convert the number to a string. *Hint:* %, Math.log.
- ★★ Exercise R4.14. This chapter contains several recommendations regarding variables and constants that make programs easier to read and maintain. Summarize these recommendations.
- ★★★ Exercise R4.15. What is a final variable? Can you define a final variable without supplying its value? (Try it out.)
- ★ Exercise R4.16. What are the values of the following expressions? In each line, assume that

```
double x = 2.5;
double y = -1.5;
int m = 18;
int n = 4;
String s = "Hello";
String t = "World";

a. x + n * y - (x + n) * y

b. m / n + m % n

c. 5 * x - n / 5

d. Math.sqrt(Math.sqrt(n))
```

(int) Math.round(x)

```
f. (int) Math.round(x) + (int) Math.round(y)
g. s + t
h. s + n
i. 1 - (1 - (1 - (1 - n))))
j. s.substring(1, 3)
k. s.length() + t.length()
```

Additional review exercises are available in WileyPLUS.

#### 17/

#### PROGRAMMING EXERCISES

★ Exercise P4.1. Enhance the CashRegister class by adding separate methods enterDollars, enterQuarters, enterDimes, enterNickels, and enterPennies.

Use this tester class:

```
public class CashRegisterTester
{
    public static void main (String[] args)
    {
        CashRegister register = new
CashRegister();
        register.recordPurchase(20.37);
        register.enterDollars(20);
        register.enterQuarters(2);
        System.out.println("Change: " +
register.giveChange());
        System.out.println("Expected: 0.13");
    }
}
```

★ Exercise P4.2. Enhance the CashRegister class so that it keeps track of the total number of items in a sale. Count all recorded purchases and supply a method

int getItemCount()

that returns the number of items of the current purchase. Remember to reset the count at the end of the purchase.

- ★★ Exercise P4.3. Implement a class IceCreamCone with methods getSurfaceArea() and getVolume(). In the constructor, supply the height and radius of the cone. Be careful when looking up the formula for the surface area—you should only include the outside area along the side of the cone since the cone has an opening on the top to hold the ice cream.
- ★★ Exercise P4.4. Write a program that prompts the user for two numbers, then prints
  - The sum
  - The difference
  - The product
  - The average
  - The distance (absolute value of the difference)
  - The maximum (the larger of the two)
  - The minimum (the smaller of the two)

To do so, implement a class

Computes the sum of the values of this pair. @return the sum of the first and second values

```
*/
public double getSum() { . . . }
. . .
```

Then implement a class PairTester that constructs a Pair object, invokes its methods, and prints the results.

- ★ Exercise P4.5. Define a class DataSet that computes the sum and average of a sequence of integers. Supply methods
  - void addValue(int x)
  - int getSum()
  - double getAverage()

*Hint*: Keep track of the sum and the count of the values.

Then write a test program DataSetTester that calls addValue four times and prints the expected and actual results.

- ★★ Exercise P4.6. Write a class DataSet that computes the largest and smallest values in a sequence of numbers. Supply methods
  - void addValue(int x)
  - int getLargest()
  - int getSmallest()

Keep track of the smallest and largest values that you've seen so far. Then use the Math.min and Math.max methods to update them in the addValue method. What should you use as initial values? *Hint*: Integer.MIN\_VALUE, Integer.MAX\_VALUE.

Write a test program DataSetTester that calls addValue four times and prints the expected and actual results.

★ Exercise P4.7. Write a program that prompts the user for a measurement in meters and then converts it into miles, feet, and inches. Use a class

```
public class Converter
```

```
/**
            Constructs a converter that can
convert between two units.
            @param aConversionFactor the factor by
which to multiply
            to convert to the target unit
      * /
      public Converter(double aConversionFactor) {
      /**
            Converts from a source measurement to
a target measurement.
            @param fromMeasurement the measurement
            @return the input value converted to
the target unit
      public double convertTo(double
                                                       175
fromMeasurement) { . . . }
                                                       176
            Converts from a target measurement to
a source measurement.
            @param toMeasurement the target
measurement
            @return the value whose conversion is
the target measurement
      public double convertFrom(double
toMeasurement) { . . . }
In your ConverterTester class, construct and test the following
Converter object:
final double MILE TO KM = 1.609;
Converter milesToMeters = new Converter(1000 *
MILE TO KM);
```

- ★ Exercise P4.8. Write a class Square whose constructor receives the length of the sides. Then supply methods to compute
  - The area and perimeter of the square
  - The length of the diagonal (use the Pythagorean theorem)

- \*\* Exercise P4.9. Implement a class SodaCan whose constructor receives the height and diameter of the soda can. Supply methods getVolume and getSurfaceArea. Supply a SodaCanTester class that tests your class.
- ★★★ Exercise P4.10. Implement a class Balloon that models a spherical balloon that is being filled with air. The constructor constructs an empty balloon. Supply these methods:
  - void addAir(double amount) adds the given amount of air
  - double getVolume() gets the current volume
  - double getSurfaceArea() gets the current surface area
  - double getRadius() gets the current radius

Supply a BalloonTester class that constructs a balloon, adds  $100 \, \mathrm{cm}^3$  of air, tests the three accessor methods, adds another  $100 \, \mathrm{cm}^3$  of air, and tests the accessor methods again.

★★ Exercise P4.11. *Giving change*. Enhance the CashRegister class so that it directs a cashier how to give change. The cash register computes the amount to be returned to the customer, in pennies.

Add the following methods to the CashRegister class:

- int giveDollars()
- int giveQuarters()
- int giveDimes()
- int giveNickels()
- int givePennies()

Each method computes the number of dollar bills or coins to return to the customer, and reduces the change due by the returned amount. You may assume that the methods are called in this order. Here is a test class:

```
public class CashRegisterTester
      public static void main(String[] args)
                                                      176
            CashRegister register = new
                                                      177
CashRegister();
            register.recordPurchase(8.37);
            register.enterPayment(10, 0, 0, 0, 0);
            System.out.println("Dollars: " +
register.giveDollars());
            System.out.println("Expected: 1");
            System.out.println("Quarters: " +
register.giveQuarters());
            System.out.println("Expected: 2");
            System.out.println("Dimes: " +
register.giveDimes());
            System.out.println("Expected: 1");
            System.out.println("Nickels: " +
register.giveNickels());
            System.out.println("Expected: 0");
            System.out.println("Pennies: " +
register.givePennies());
            System.out.println("Expected: 3");
      }
```

★★★ Exercise P4.12. Write a program that reads in an integer and breaks it into a sequence of individual digits in reverse order. For example, the input 16384 is displayed as

4 8 3

6

You may assume that the input has no more than five digits and is not negative.

```
Define a class DigitExtractor:
     public class DigitExtractor
                Constructs a digit extractor that gets the digits
                of an integer in reverse order.
                @param anInteger the integer to break up into digits
             public DigitExtractor(int anInteger) { . .
      . }
                Returns the next digit to be extracted.
                Oreturn the next digit
             public int nextDigit() { . . . }
      }
     In your main class DigitPrinter, call
     System.out.println(myExtractor.nextDigit()) five
     times.
★★ Exercise P4.13. Implement a class Quadratic Equation whose
   constructor receives the coefficients a, b, c of the quadratic equation ax^2 +
   bx + c = 0. Supply methods getSolution1 and getSolution2 that
   get the solutions, using the quadratic formula. Write a test class
    QuadraticEquationTester that constructs a
    QuadraticEquation object, and prints the two solutions.
                                                                         177
                                                                         178
** Exercise P4.14. Write a program that reads two times in military format
     (0900, 1730) and prints the number of hours and minutes between the
     two times. Here is a sample run. User input is in color.
     Please enter the first time: 0900
     Please enter the second time: 1730
     8 hours 30 minutes
     Extra credit if you can deal with the case where the first time is later than
     the second time:
```

Please enter the first time: 1730

```
Please enter the second time: 0900 15 hours 30 minutes
```

Implement a class TimeInterval whose constructor takes two military times. The class should have two methods getHours and getMinutes.

★ Exercise P4.15. Writing large letters. A large letter H can be produced like this:

Use the class

```
public class LetterH
{
         public String toString()
         {
            return
"* *\n* *\n****\n* *\n* *\n";
         }
}
```

Define similar classes for the letters E, L, and O. Then write the message

H E L L

in large letters.

Your main class should be called HelloPrinter.

★★ Exercise P4.16. Write a class ChristmasTree whose toString method yields a string depicting a Christmas tree:

Remember to use escape sequences.

- ★★ Exercise P4.17. Your job is to transform numbers 1, 2, 3, ..., 12 into the corresponding month names January, February, March, . . . , December. Implement a class Month whose constructor parameter is the month number and whose getName method returns the month name. Hint: Make a very long string "January February March ... ", in which you add spaces such that each month name has the same length. Then use substring to extract the month you want.
- ★★ Exercise P4.18. Write a class to compute the date of Easter Sunday. Easter Sunday is the first Sunday after the first full moon of spring. Use this algorithm, invented by the mathematician Carl Friedrich Gauss in 1800:
  - 1. Let y be the year (such as 1800 or 2001).
  - 2. Divide y by 19 and call the remainder a. Ignore the quotient.
  - 3. Divide y by 100 to get a quotient b and a remainder c.
  - **4.** Divide b by 4 to get a quotient d and a remainder e.
  - 5. Divide 8 \* b + 13 by 25 to get a quotient g. Ignore the remainder.
  - **6.** Divide 19 \* a + b d g + 15 by 30 to get a remainder h. Ignore the quotient.
  - 7. Divide c by 4 to get a quotient  $\dot{j}$  and a remainder k.
  - **8.** Divide a + 11 \* h by 319 to get a quotient m. Ignore the remainder.

- 9. Divide 2 \* e + 2 \* j k h + m + 32 by 7 to get a remainder r. Ignore the quotient.
- **10.** Divide h m + r + 90 by 25 to get a quotient n. Ignore the remainder.
- 11. Divide h m + r + n + 19 by 32 to get a remainder p. Ignore the quotient.

Then Easter falls on day p of month n. For example, if y is 2001:

$$a = 6$$
  $g = 6$   $r = 6$   
 $b = 20$   $h = 18$   $n = 4$   
 $c = 1$   $j = 0$ ,  $k = 1$   $P = 15$   
 $d = 5$ ,  $e = 0$ 

Therefore, in 2001, Easter Sunday fell on April 15. Write a class Easter with methods getEasterSundayMonth and getEasterSundayDay.

Additional programming exercises are available in WileyPLUS.

# **PROGRAMMING PROJECTS**

 $\star\star\star$  **Project 4.1** In this project, you will perform calculations with triangles. A triangle is defined by the *x*- and *y*-coordinates of its three corner points.

Your job is to compute the following properties of a given triangle:

- the lengths of all sides
- the angles at all corners
- the perimeter
- the area 179

Of course, you should implement a Triangle class with appropriate methods. Supply a program that prompts a user for the corner point

coordinates and produces a nicely formatted table of the triangle properties.

This is a good team project for two students. Both students should agree on the Triangle interface. One student implements the Triangle class, the other simultaneously implements the user interaction and formatting.

\*\*\* Project 4.2 The CashRegister class has an unfortunate limitation: It is closely tied to the coin system in the United States and Canada.

Research the system used in most of Europe. Your goal is to produce a cash register that works with euros and cents. Rather than designing another limited CashRegister implementation for the European market, you should design a separate Coin class and a cash register that can work with coins of all types.

# **ANSWERS TO SELF-CHECK QUESTIONS**

- 1. int and double.
- 2. When the fractional part of x is  $\ge 0.5$ .
- 3. By using a cast: (int) Math.round(x).
- **4.** The first definition is used inside a method, the second inside a class.
- **5.**
- (1) You should use a named constant, not the "magic number" 3.14.
- (2) 3.14 is not an accurate representation of  $\pi$ .
- **6.** The statement adds the amount value to the balance variable.
- 7. One less than it was before.
- **8.** 17 and 29.
- 9. Only s3 is divided by 3. To get the correct result, use parentheses. Moreover, if s1, s2, and s3 are integers, you must divide by 3.0 to avoid integer division:

$$(s1 + s2 + s3) / 3.0$$

**10.** 
$$\sqrt{x^2 + y^2}$$

- 11.  $\times$  is a number, not an object, and you cannot invoke methods on numbers.
- 12. No—the println method is called on the object System.out.
- 13. s is set to the string Agent 5.
- 14. The strings "i" and "ssissi".
- **15.** The class only has a method to read a single byte. It would be very tedious to form characters, strings, and numbers from those bytes.
- **16.** The value is "John". The next method reads the next word.
